

Summary of IR Upgrade Status & Beam-Beam

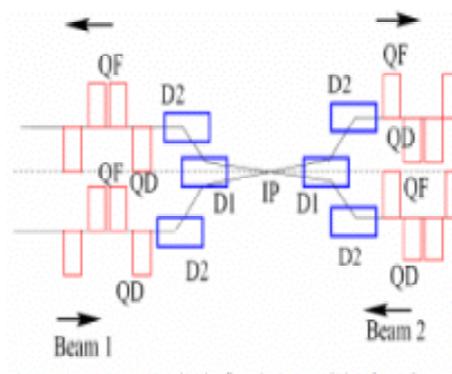

(LARP Collaboration Meeting, April, 2006)

John A. Johnstone

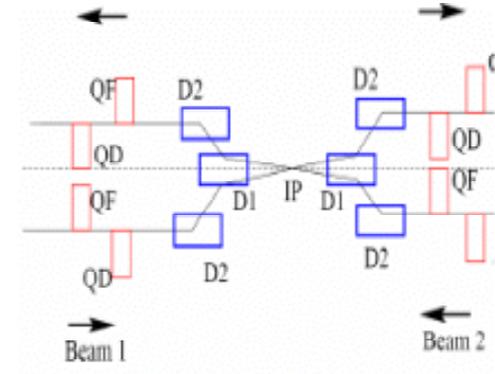

- 3 basic configurations are under consideration:

Triplet quads first

Dipoles first & triplets

Dipoles first & doublets

- It had been proposed that IR designs should be evaluated based on the criteria:
 - (i) Luminosity reach;
 - (ii) R&D time for critical hardware, and;
 - (iii) Operational time required to implement an upgrade scheme into routine operations.
- A repository of the various layouts is maintained for study at CERN containing lattice files, plots of apertures, and optics functions. The goal being to deliver a baseline upgrade scenario by the end of 2006.
- The general concensus at the LARP meeting seemed to be that the rating criteria are too simplistic. "Luminosity Reach", in particular, is an ill-defined concept, and the interplay of many complex parameters must be evaluated, e.g:
 - magnet fields & apertures
 - energy deposition
 - beam-beam interactions
 - susceptibility to random noise - ground motion, power supply ripple, etc.
 - closest approach of magnets to the IP (L^*)
 -

Sampling of IR Issues Discussed:

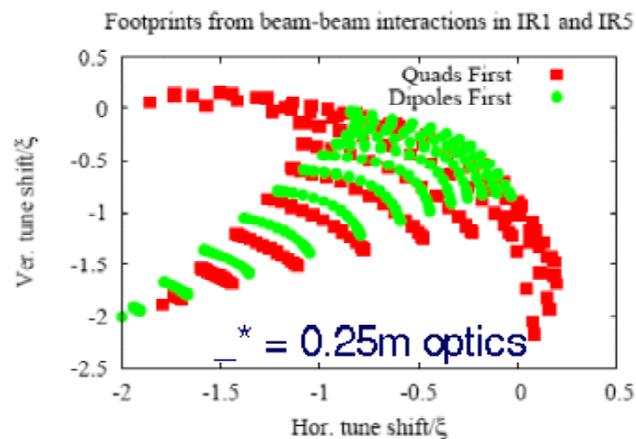

- All 3 schemes require quad apertures >100 mm, which implies Nb₃Sn technology.

- Quadrupoles first:

Advantages are the minimum operational times required to implement successfully, and the greatest luminosity benefits achieved by reducing L^* .

- Dipoles first & triplet optics:

Major motivation is the smaller number of long-range beam-beam interactions (~ 12 per IR, compared to ~ 30 with quads first).

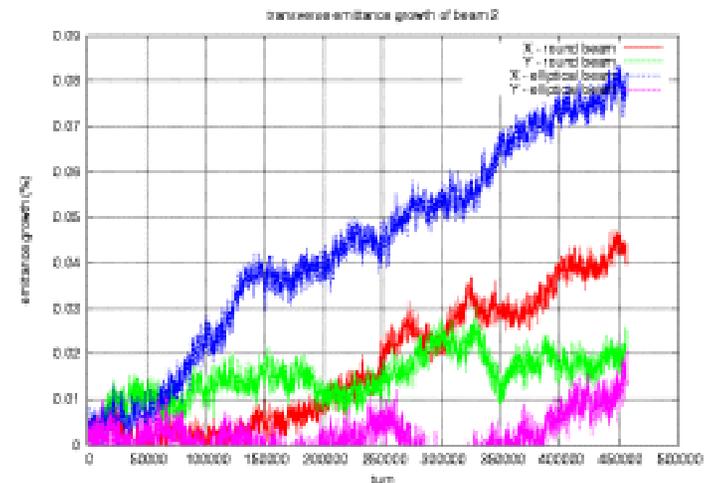

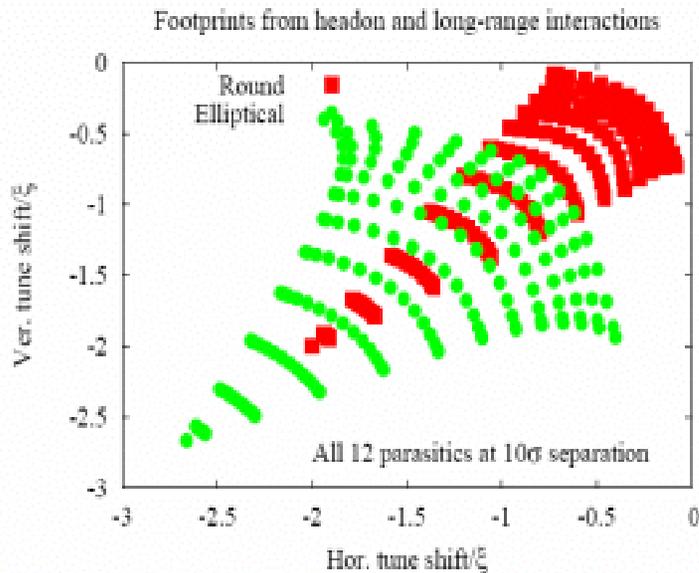

- Do the 'wings' have an adverse impact?
Needs to be studied with simulations.
- If wire compensation is shown to be effective this may not be a concern.

- Dipoles first & doublet optics:

Doublets produce elliptical beams at the IP, giving a luminosity increase $>30\%$ for equivalent β^* to round beams & same β_{\max} (reduced crossing angle in plane of larger β^*).

Beam-beam behavior is different from round beams:

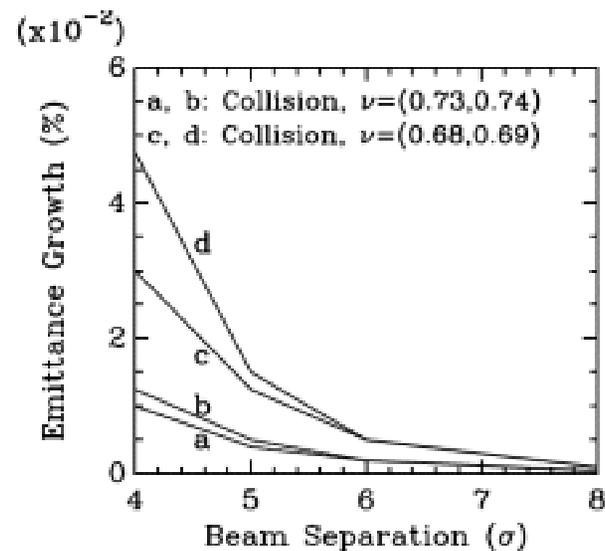

Elliptical beam have a larger footprint

Emittance growth from head-on collisions is larger for elliptical beams (J. Qiang)

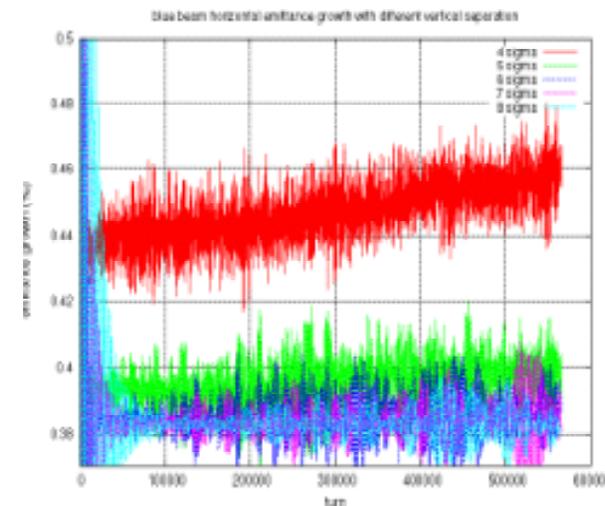

- Doublet optics need more analysis before becoming a truly viable candidate.

RHIC Beam-Beam Experiments & Simulations:

- Beam-beam experiments are intended to quantitatively answer whether a single parasitic causes beam losses that need to be compensated, leading to test of wire compensation in 2007.
- Wire compensator has been designed.
- Simulations are being performed at FNAL, SLAC, LBL, and U. Kansas to improve codes & predict RHIC observations and effects of wire compensation.

Emittance growth with beam separation
& working point (U. Kansas)

Emittance growth with vertical separation
- cliff at $\sim 5\sigma$ (LBL)

Summary of IR Summary

- IR optics layouts have been proposed, with a lattice repository at CERN. The goal is to rate IR designs with an eye to defining a baseline scenario by the end of 2006(!).
- Beam-beam simulations will be helpful in deciding between IR configurations.
- Beam-beam experiments have been started at RHIC & initial beam-beam simulation results have been reported by several groups.
- Both wire compensators will be installed in RHIC during the 2006 shutdown, and first tests with beams are scheduled for 2007.
